

WHO IS MORE AFFECTED? DEMOGRAPHIC PATTERNS OF ANXIETY AND DEPRESSION

This poster uses data from the *Household Pulse Survey* (U.S. Census Bureau, CDC, NCHS) to visualize anxiety and depression symptom rates across demographic groups. The analysis highlights population-level patterns, demographic disparities, and temporal trends using percentage estimates and confidence intervals.

Females report higher anxiety and depressive symptom levels than males. The gender difference is particularly strong for anxiety, with a much higher median and a very large effect size, while the difference in depression is smaller but still statistically significant. Overall, gender disparities are more pronounced for anxiety than for depression.

Mental health symptom prevalence is highest in young adults and decreases consistently with age.

States are ordered by their median symptom rates, which allows for clear and intuitive comparison and makes the plot easier to read. The ridgeline densities illustrate both the typical symptom levels and the spread within each state, showing that while many states share similar central tendencies, the variability and upper tails differ noticeably. Overall, the figure emphasizes substantial geographic heterogeneity in reported anxiety and depression symptoms.

Anxiety and depression symptoms show a clear decreasing trend with increasing education level. Estimates are presented with 95% confidence intervals, revealing both higher symptom prevalence and greater variability among individuals with lower educational attainment.
